Joint planning of transmission grid and energy storage

Overview

Hence, this paper first decouples the insufficient flexibility and transmission congestion wind power curtailment, and quantitatively analyzes the impact of transmission capacity on the coupling relationship between the two; second, reveals the principle of joint planning of energy storage system and transmission congestion, and constructs an optimization model, and proposes to set up the capacity of the wind power which connects the power network. Which scenario uses a single transmission grid planning method?

Scenario 2 utilizes a single transmission grid planning method as described in [14, 15], without considering energy storage planning. Scenario 3 presents the multi-stage coordinated planning of energy storage and transmission networks proposed in this paper, characterized as dynamic planning.

Should energy storage and transmission lines be coordinated?

However, most existing studies on the coordinated planning of energy storage and transmission lines are based on static planning. They implement a one-time planning process from the current state to the target year, failing to consider the gradual growth of load demand and renewable energy capacity.

How can we quantify the delay in New grid line capacity construction?

Reference proposes a method to quantify the delay in new grid line capacity construction using distributed generation, including energy storage. Reference proposes a collaborative planning model for transmission networks and compressed air energy storage.

What is a multi-stage collaborative planning model for transmission networks and energy storage?

A multi-stage collaborative planning model for transmission networks and energy storage that considers the acceptance capacity of renewable energy is established. The model aims to minimize the total system cost while considering the mutual influences between different planning stages.

What is a multi-stage coordinated expansion planning scheme?

Multi-stage coordinated expansion planning scheme for transmission network and energy storage, and associated costs.

Will a single-step collaborative planning scheme lead to over-investment of transmission lines?

The single-step static collaborative planning scheme of transmission network and energy storage will result in “over-investment” of transmission lines and energy storage, that is, the amount of transmission line expansion and energy storage configuration far exceeds the transmission capacity demand corresponding to the current load.
