Lithium battery packs have the same values for both groups

Overview

Battery packs for cars, laptops, E-bikes etc. are all assembled from batteries that are very similar, preferably from the same batch. Then the voltages, capacities and series resistances should match well enough to assemble a battery pack without issues.

Battery packs for cars, laptops, E-bikes etc. are all assembled from batteries that are very similar, preferably from the same batch. Then the voltages, capacities and series resistances should match well enough to assemble a battery pack without issues.

When matching li-ion cells in a battery pack how do you use both the cell's resistance AND capacity?

I've seen sources mentioning that each parallel group should have about the same capacity, and that cell internal resistances should be "close". How do we match based on both criteria?

Say I want to.

A lithium battery pack is a combination of individual lithium-ion cells. These cells work together to provide the necessary power for various applications. How these cells are connected—whether in series, parallel, or a combination of both—determines the overall voltage and capacity of the battery.

Cells 1-12 have the same value of $h = 30 \text{ W}$ / Cell 15 always receives the highest current for both charge and discharge and the peak current variation reaches to 21.8%. Innovative modeling approach for Li-ion battery packs considering intrinsic cell unbalances and packaging. Elements (2019).

Balancing lithium batteries in parallel involves measuring each battery's voltage before connection, ensuring they're within an acceptable range of each other, and then connecting all positive and negative terminals together. What Does It Mean For Lithium Batteries To Be Balanced?

Battery balancing.

Tesla battery packs consists of paralleled cells. TL:DR so I did not watch the video but the application is sound. As long as the batteries are at the same state of charge when connected and the same chemistry then there should not be a problem. As to why it works, here is how I understand it. It.

This combination of cells is called a battery. Sometimes battery packs are used in both configurations together to get the desired voltage and high capacity. This configuration is found in the laptop battery, which has four Li-ion cells of 3.6 V connected in series to get 14.4 V. Each cell has one.

Lithium battery packs have the same values for both groups
